1.0 INTRODUCTION

Powerine Oil Company (POC) owns and operates a petroleum refinery located at 12354 Lakeland Road in Santa Fe Springs, California (Figure 1). The POC refinery has historically processed crude oil to make several grades of petroleum, including diesel, gasoline, and jet fuel. Powerine expects to resume operations of the refinery some time in 1997.

Groundwater quality monitoring is being conducted semiannually at POC. This report presents: the results of the monitoring event conducted in December 1996; field and analytical data collected from POC and Walker Property wells; and a study of groundwater intrinsic bioremediation/natural attenuation indicators. POC has prepared this report to satisfy the requirements of the semiannual groundwater monitoring program as directed by the State of California, Los Angeles Region, Regional Water Quality Control Board (LARWQCB).

The semiannual groundwater monitoring well network at POC currently consists of three up-gradient wells (MW-104, MW-105 and MW-106), twenty refinery and down-gradient wells, and four wells (W-1, W-2, W-3, and W-4) located on the nearby Walker Property (Figure 1).

2.0 GROUNDWATER FLOW

Fluid levels and total well depths were measured in all POC monitoring wells as part of the semiannual monitoring event. Fluid levels were measured using an oil water interface meter to verify the presence/absence of light non aqueous phase liquid (LNAPL). Based on previous water quality data for the site, fluid levels were measured in order of increasing groundwater contamination to reduce the possibility of cross contamination. Recent and historical groundwater elevation data are summarized in Table A-1 in Appendix A. As indicated on Table A-1, LNAPL was detected in two monitoring wells during this sampling event; Well MW-504 (0.3 feet) and Well MW-600 (2.55 feet). No LNAPL was detected in Well MW-601, which contained 0.28 feet of product during the previous monitoring event.

A groundwater elevation contour map was constructed using the fluid-level data collected in December 1996 (Figure 2). Prior to constructing the groundwater elevation contour map, fluid levels in both monitoring wells containing LNAPL were corrected to account for the presence of LNAPL on the groundwater. An average specific gravity of 0.75 was used as the correction factor (Table A-1).

As shown on Figure 2, groundwater in the vicinity of POC generally flows toward the south. Based on the December 1996 fluid level data, the hydraulic gradient underlying the site is approximately 0.008 feet/foot.

3.0 GROUNDWATER QUALITY

Groundwater samples were collected from 27 monitoring wells located at POC and nearby properties from December 16 through December 19, 1996. Samples were collected for analysis of benzene, toluene, ethylbenzene, total xylenes (BTEX), methyl-tertiary butyl ether (MTBE) and chlorinated hydrocarbons by EPA Method 8260, and total petroleum hydrocarbons as gasoline (TPH-G) by Modified EPA Method 8015. Blakely Environmental Investigations, Inc. (Wrightwood, California) also collected samples in support of a natural attenuation study. Their report is presented in Appendix C. Groundwater monitoring procedures used and the results of the December 1996 sampling event are discussed below.

3.1 Water Quality Monitoring Procedures

Groundwater sample collection procedures and field quality control procedures consisted of the following:

- Monitoring wells were sampled in order of increasing contamination based on historical water quality data to reduce cross contamination.
- Each monitoring well was purged with a decontaminated PVC bailer until the field parameters (specific conductivity, pH, and temperature) stabilized. At least one casing volume of standing water was removed from the well prior to the first field parameter measurement.
- One field blank and one equipment blank were collected each day sampling activities were conducted. The field blank was made up of reagent free distilled water and the equipment blank was made up of the same distilled water rinsate used in the decontamination of the sampling bailer.
- After field parameters had stabilized (two consecutive measurements within 10%), a stainless steel sampling bailer was lowered into the monitoring well and the sample was collected.

Field parameters were measured on the groundwater sample from each monitoring well immediately following sample collection by field personnel. Laboratory analyses (EPA methods 8260 and Modified 8015) were performed by Core Laboratories of Anaheim, California.

3.2 Water Quality Results

The results of the water quality analyses for BTEX/MTBE, TPH-G, and chlorinated hydrocarbons are summarized in data tables presented in Appendix A. A benzene isoconcentration map is presented on Figure 3. An isoconcentration map for total petroleum hydrocarbons as gasoline is presented on Figure 4. An isoconcentration map for toluene was not produced due to a lack of detected toluene during this monitoring event. Laboratory

analytical reports and groundwater quality field records are presented in Appendix B. The types and levels of hydrocarbon constituents detected in the monitoring wells were similar to previous monitoring results.

3.3 Quality Control Results

Quality control samples analyzed during the December 1996 sampling event included four field blanks and four equipment blanks. One field blank and one equipment blank were collected for each day samples were collected. Analytical results for the quality control samples are included in the laboratory analytical report presented in Appendix B. Generally, the analytical data from this monitoring event are consistent with analytical data from previous events.

Although there were anomalies in some of the laboratory QA/QC results, these anomalies did not affect the overall integrity of the reported analytical results from the groundwater monitoring wells. Groundwater samples from wells MW-600, MW-601, and W-2 were analyzed by the laboratory for EPA Method 8260 up to three days after the fourteen-day holding time had expired. The groundwater sample from Well W-2 was also analyzed for TPH-G two days after the fourteen day holding time had expired. Laboratory results for the groundwater samples from wells MW-600 and MW-601 were comparable with previous groundwater analytical results from these wells. POC does not have historical TPH-G or Method 8260 data from the Walker Property Well W-2, but will obtain groundwater analyses from this location during the next monitoring event. The surrogate recovery for the MTBE analyses on the groundwater sample from Well MW-101 was outside acceptable ranges (by one percentage point) due to matrix effects. However, MTBE was not detected in the groundwater sample from this well, a result which is consistent with historical groundwater analytical data.

4.0 FUTURE ACTIVITIES

The next semiannual groundwater monitoring event is scheduled for June, 1997.

Anaheim, CA 92805

Title: LABORATORY MANAGER

CORE LABORATORIES

**CASE NARRATIVE
CORE JOB# 962972**

Sample 962972-0031, 0034, 0035 (MW-2, MW-600, MW-601)
w-2 1/8

The analyses reported for the above samples were performed after the holding time expired. These analyses were necessary due to the target analyte concentrations that were above the instrument calibration range. All original analyses were performed within the method holding time.

COMMENTS

All methods of chemical analysis have a statistical uncertainty associated with the results. Unless otherwise indicated, the data in this report are within the limits of uncertainty as specified in the referenced method. Quality control acceptance criteria are based either on actual laboratory performance or on limits specified in the referenced method. The date and time of analysis indicated on the QA report may not reflect the actual time of analysis for QC samples. All data reported on an "as received" basis unless otherwise indicated. Data reported in the QA report may be lower than sample data due to dilution of samples into the calibration range of the analysis. Sample concentrations for solid samples are calculated on an as received (wet) basis. Unless otherwise indicated, volatiles by gas chromatography are reported from a single column. Volatiles analyses on low level soils are conducted at room temperature.

FLAGS, FOOTNOTES, AND ABBREVIATIONS (as needed)

NA = Not analyzed N.I. = Not Ignitable
 N/A = Not applicable S.I. = Sustains Ignition
 ug/L = Micrograms per liter I(NS) = Ignites, but does not Sustain Ignition
 mg/L = Milligrams per liter RPD = Relative Percent Difference
 ND = Not detected at a value greater than the reporting limit
 NC = Not calculable due to values lower than the detection limit
 (a) = Surrogate recoveries were outside acceptable ranges due to matrix effects.
 (b) = Surrogate recoveries were not calculated due to dilution of the sample below the detectable range for the surrogate.
 (c) = Matrix spike recoveries were outside acceptable ranges due to matrix effects.
 (d) = Relative Percent Difference (RPD) for duplicate analysis outside acceptance limits due to actual differences in the sample matrix.
 (e) = The limit listed for flammability indicates the upper limit for the test. Samples are not tested at temperatures above 140 Fahrenheit since only samples which will sustain ignition at temperatures below 140 are considered flammable.
 (f) = Results for this hydrocarbon range did not match a typical hydrocarbon pattern. Results were quantified using a diesel standard, however, the hydrocarbon pattern did not match a diesel pattern.
 (g) = Results for this hydrocarbon range did not match a typical hydrocarbon pattern. Results were quantified using a gasoline standard, however, the hydrocarbon pattern did not match a gasoline pattern.
 (h) = High dilution due to matrix effects
 (i) = Samples with results below 500 mg/L are considered hazardous

QC SAMPLE IDENTIFICATIONS

MB = Method Blank	SB = Storage Blank
RB = Reagent Blank	MS = Matrix Spike
ICB = Initial Calibration Blank	MSD = Matrix Spike Duplicate
CCB = Continuing Calibration Blank	MD = Matrix Duplicate
CS = Calibration Standard	BS = Blank Spike
ICB = Initial Calibration	SS = Surrogate Spike
Verification	LCS = Laboratory Control
CCV = Continuing Calibration	Standard
Verification	RS = Reference Standard

1.0 Introduction

Blakely Environmental Investigations, Inc. (BEI, Inc.) was contracted by Powerine Oil Company to identify intrinsic bioremediation of petroleum hydrocarbon aromatic constituents dissolved in groundwater underlaying the refinery site located at 12354 Lakeland Road, Santa Fe Springs, California and at the Walker Property located at the southeast parcel at the intersection of Lakeland Road and Bloomfield Avenue. Measurement of intrinsic biodegradation of the mass of petroleum hydrocarbon constituents dissolved in the groundwater will be accomplished by monitoring depletion of aerobic and anaerobic electron acceptors in areas of groundwater which have been impacted by petroleum hydrocarbons. Initially, dissolved oxygen, the primary electron receptor necessary for petroleum biodegradation, will be the exclusive electron receptor monitored until depletion. At that time lesser preferred electron receptors (nitrate, sulfate, and iron (III)) will be monitored for measurement of petroleum aromatic constituent mass biodegraded by anaerobic processes in the absence of dissolved oxygen. As dissolved oxygen remains available, the microbiological aerobic petroleum degradation process will be characterized through monitoring of the metabolic by-product carbon dioxide to indicate mass reduction of petroleum hydrocarbons. Similar dissolved phase petroleum hydrocarbon impacted sites have shown a distribution of electron receptors, metabolites and dissolved petroleum aromatic constituents demonstrating that aerobic respiration is, initially, the dominant terminal electron accepting process. Further, at similarly impacted sites, anaerobic biodegradation has effectively reduced dissolved petroleum hydrocarbon aromatic constituent mass where replenishment of dissolved oxygen has not been sufficient for aerobic respiration. Therefore, during successive monitoring episodes, lesser preferred biodegradation processes may be evaluated depending upon the anticipated significance of each process.

2.0 Aerobic Biodegradation

Testing for aerobic biodegradation is performed using the Expressed Assimilative Capacity (EAC) for dissolved oxygen, the dominant TEAP (terminal electron accepting process) of aerobic biodegradation. The EAC for a given TEAP is the amount of petroleum hydrocarbon contamination, such as BTEX (benzene, toluene, ethylbenzene, and xylene), that a body of groundwater has shown it has degraded using the stoichiometry of the oxidation reaction. The EAC for aerobic biodegradation of dissolved benzene is derived from the following reaction:

From the stoichiometry of aerobic benzene biodegradation, 3.08 mg of oxygen are required to completely metabolize 1 mg of benzene and 1 mg of dissolved oxygen is capable of facilitating the destruction of 0.32 mg of benzene (Wiedemeier, Miller, Wilson, Campbell, 1995). Similar calculations can be made using the stoichiometry for toluene, ethylbenzene, and xylene

**Powerine Oil Company
Monitoring Report
01-02-97
Page 2**

aerobic biodegradation reactions. Using the average mass ratio of dissolved oxygen to total BTEX from the individual compound biodegradation stoichiometry, 1 mg of dissolved oxygen is therefore required to metabolize 0.32 mg of total BTEX. The EAC of groundwater for aerobic respiration is determined as follows:

$$EAC_{DO} = 0.32 (O_B - O_M)$$

Where: EAC_{DO} = Expressed Assimilative Capacity, aerobic respiration.
 0.32 = mg/L BTEX degraded per mg/L dissolved oxygen consumed ratio.
 O_B = background dissolved oxygen concentration (mg/L).
 O_M = dissolved oxygen concentration in plume (mg/L).

A reduction in dissolved oxygen and BTEX concentrations within an existing BTEX plume is a strong indication that indigenous microbes are established and actively biodegrading petroleum hydrocarbons via aerobic respiration.

3.0 Collection of Biodegradation Indicators

BEI, Inc. collected groundwater samples and analyzed biodegradation indicators in conjunction with groundwater sample collection by TriHydro Corporation from December 17, 1996 to December 19, 1996, to monitor the progress of aerobic intrinsic bioremediation of dissolved phase petroleum hydrocarbons. Dissolved carbon dioxide, dissolved oxygen and redox potential measurements were collected from groundwater to determine if subsurface conditions favor aerobic respiration. Aerobic biodegradation will remain the dominant TEAP until dissolved oxygen becomes limited in the dissolved petroleum hydrocarbon plume.

Two (2) 0.5 liter laboratory supplied sampling jars were filled with groundwater from each well for dissolved carbon dioxide laboratory analysis. Dissolved oxygen and redox potential were measured in the field using a YSI Model 55 and an Orion Model 290A with an Orion Redox Electrode, respectively. A portion of groundwater retrieved for sampling was cautiously poured in a jar containing the dissolved oxygen probe and redox electrode to minimize disturbances. The jar was also capped to minimize exposure to the ambient air. Dissolved oxygen and redox potential readings were recorded immediately following stabilization. Each instrument was calibrated on a daily basis to insure consistency in readings.

4.0 Dissolved Oxygen Results

Dissolved oxygen measurements obtained during this monitoring episode are tabulated along with dissolved benzene concentrations in Table 1.

**Powerine Oil Company
Monitoring Report
01-02-97
Page 4**

Effective aerobic biodegradation of dissolved phase petroleum hydrocarbons requires sufficient dissolved oxygen to sustain aerobic microbial respiration for β -carbon cleavage of the petroleum hydrocarbon alkanes and cis-hydroxylation of aromatic petroleum hydrocarbons. Sufficient dissolved oxygen content occurs when the ratio of dissolved oxygen concentration to dissolved petroleum hydrocarbon concentrations in groundwater reaches 3:1 (Wiedemeier, Miller, Wilson, Kampbell, 1995). Aerobic biodegradation can be sustained as long as the dissolved oxygen concentration is maintained above the critical concentration of 0.5 mg/L; dissolved oxygen levels below 0.5 mg/L may favor anaerobic microbial activity (Riser-Roberts, 1992). The background level of dissolved oxygen beneath the site was identified as 4.9 mg/L in MW-606 which had no detectable levels of dissolved petroleum hydrocarbons.

This study is focused upon mass removal of dissolved benzene caused by intrinsic biodegradation. Dissolved benzene has been monitored since this is the most miscible and most mobile of the petroleum aromatic constituents tested. Benzene concentrations are monitored to identify the leading migratory edge of the dissolved gasoline constituents due to its relatively high water solubility of 1780 micrograms per liter ($\mu\text{g}/\text{L}$).

Based on 3:1 dissolved oxygen level to dissolved benzene concentration ratio, effective intrinsic bioremediation of dissolved phase petroleum hydrocarbons is occurring in the following 21 of the 25 wells monitored: MW-101, MW-103, MW-104, MW-105, MW-106, MW-107, MW-201, MW-202, MW-203, MW-204, MW-205, MW-503, MW-603, MW-604, MW-605, MW-606, MW-607, W-1, W-2, W-3, and W-4. Dissolved oxygen concentrations are, at a minimum, three times the concentration of dissolved phase benzene in each of these monitoring wells. Monitoring wells MW-605 and MW-606 identified no detectable concentrations of benzene and dissolved oxygen levels are sufficient in these wells for sustainable aerobic biodegradation.

Samples from monitoring wells MW-206, MW-501, MW-502, and MW-601 contained dissolved oxygen to dissolved benzene concentration ratios at less than 3:1. However, aerobic intrinsic biodegradation in these six wells is still the more favorable mechanism for petroleum hydrocarbon reduction since dissolved oxygen levels exceed the critical concentration of 0.5 mg/L needed for aerobic microbial activity. Further monitoring and analysis of dissolved oxygen to dissolved benzene ratios are recommended to confirm aerobic intrinsic bioremediation.

5.0 Dissolved Carbon Dioxide Results

Dissolved carbon dioxide concentrations obtained during this monitoring episode are tabulated along with dissolved oxygen and benzene concentrations in Table 2. Laboratory analytical reports are included as Attachment 1.

Page 6

Dissolved carbon dioxide, a by-product of microbial aerobic biodegradation of dissolved phase petroleum hydrocarbons, is monitored and used as an indicator of dissolved petroleum hydrocarbon mass reduction from intrinsic bioremediation. Elevated levels of dissolved carbon dioxide, where dissolved benzene and adequate dissolved oxygen levels for microbial respiration are identified, indicate effective intrinsic biodegradation. Dissolved carbon dioxide background levels in groundwater beneath the facility average approximately 38 mg/L as identified by monitoring well MW-606, which had the maximum dissolved oxygen concentration and no detectable levels of dissolved phase petroleum hydrocarbons to influence dissolved carbon dioxide equilibrium.

Based on dissolved carbon dioxide levels, dissolved oxygen levels, and dissolved benzene concentrations, intrinsic bioremediation of dissolved phase petroleum hydrocarbons is occurring by aerobic microbial respiration in 19 of 25 monitoring wells. The elevated carbon dioxide levels, a by-product of respiration, identified in 19 wells suggest the occurrence of microbial respiration. The availability of dissolved oxygen levels above 0.5 mg/L and a dissolved oxygen to dissolved benzene ratio of 3:1 identified in the 19 wells, supports the occurrence and sustain ability of microbial respiration. The dissolved benzene concentrations identified in the 19 wells serve as a food source for continuing microbial respiration. These monitoring wells identified dissolved carbon dioxide levels at greater than background levels, sufficient dissolved oxygen levels to sustain aerobic biodegradation, and dissolved benzene concentrations to supply a food source for petroleum degrading microbes.

Monitoring wells MW-206, MW-501, MW-502, and MW-601 identified dissolved oxygen levels above 0.5 mg/L, however, dissolved oxygen to dissolved benzene ratios are less than 3:1. Aerobic biodegradation in these four wells is less effective than those in the other 21 wells monitored. Monitoring for anaerobic biodegradation indicators is recommended to confirm intrinsic, effective, anaerobic petroleum aromatic constituent mass removal by biodegradation .

6.0 Redox Potential

Redox potential measurements obtained during this monitoring episode are tabulated in Table 3.

Redox potential is the measurement of electron transfer from one ion to another via an electrical current. A positive redox potential is indicative of an oxidation reaction while a negative redox potential indicates a reducing reaction.

Based on combined positive redox potential readings and high O₂ to C₆H₆ ratios, aerobic biodegradation is occurring in monitoring wells MW-104, MW-105, MW-603, MW-604, MW-605, MW-607, and W-1. The remaining monitoring wells identified negative redox potentials indicative of dormant oxidation states, either due to attenuated levels of dissolved oxygen available or to insufficient dissolved petroleum hydrocarbon food source available for aerobic microbe consumption. In twenty-one (21) of twenty-five (25) monitoring wells tested, sufficient dissolved oxygen was identified for effective aerobic biodegradation of the dissolved petroleum aromatics. It is anticipated that anaerobic biodegradation has become the dominant biodegradation process occurring in the remaining four (4) monitoring wells (MW-206, MW-501, MW-502, and MW-601) where dissolved oxygen has not replenished to levels (greater than three times benzene concentrations) necessary for effective aerobic biodegradation. As identified in long term monitoring at similar sites with similar subsurface conditions, anaerobic biodegradation processes will effectively remove in excess of ninety percent (90 %) of the petroleum mass dissolved in groundwater where low replenishment of dissolved oxygen limits effective aerobic respiration.

7.0 Estimated Assimilative Capacity

The EAC for a given TEAP is the amount of petroleum hydrocarbon contamination, such as BTEX (benzene, toluene, ethylbenzene, and xylene), that a body of groundwater has shown it has degraded using the stoichiometry of the oxidation reaction. Background dissolved oxygen concentrations and dissolved oxygen concentrations in the dissolved BTEX plume were identified as follows:

$$\begin{aligned}O_B &= 4.9 \text{ mg/L} \\O_M &= 1.82 \text{ mg/L}\end{aligned}$$

Based on the background dissolved oxygen level and plume dissolved oxygen level, the aerobic biodegradation estimated assimilative capacity for the plume is as follows:

$$EAC_{DO} = 0.32 (4.9 - 1.82) = 0.9856 \text{ mg/L of BTEX}$$

The groundwater beneath the site has the capacity to biodegrade 985.6 µg/L of BTEX via aerobic respiration. A reduction in dissolved oxygen and BTEX concentrations within an existing BTEX plume is a strong indication that indigenous microbes are established and actively

biodegrading petroleum hydrocarbons via aerobic respiration.

8.0 Recommendations

BEI, Inc. recommends that the Powerine Oil Company continue to monitor indicators of intrinsic biodegradation for determination of petroleum aromatic mass removal as effective remediation of petroleum impacted groundwater. Dissolved petroleum hydrocarbon aromatic constituent mass removed by biodegradation will be quantified allowing determination of time estimates for completion of remediation. In addition, sustainable and effective intrinsic bioremediation will be demonstrated in locations where it is occurring. Those monitoring wells where dissolved oxygen to dissolved benzene ratios are less than 3:1 and where oxidation states are dormant will be analyzed for anaerobic biodegradation indicators. As identified at similarly impacted sites, anaerobic biodegradation processes will effectively remove greater than 90 % of the dissolved petroleum aromatic mass where oxygen replenishment is limited. As demonstrated at similarly impacted sites with similar subsurface conditions, aggregate aerobic and anaerobic biodegradation process provide effective remediation of dissolved petroleum hydrocarbon constituents considered potentially hazardous.
